## Abstract

The relationship between environmental protection (EP), the economy, and jobs has been an issue of harsh contention for decades. Does EP harm the economy and destroy jobs or facilitate economic growth and create jobs? We address this issue by summarizing the results of the Jobs and the Environment Initiative, research funded by nonprofit foundations to quantify the relationship between EP, the economy, and jobs. We estimate the size of the US environmental industry and the numbers of environment-related jobs at the national level and in the states of Florida, Michigan, Minnesota, North Carolina, Ohio, and Wisconsin. This is the first time that such comprehensive, detailed estimates have been developed.

Our major finding is that, contrary to conventional wisdom, EP, economic growth, and jobs creation are complementary and compatible: Investments in EP create jobs and displace jobs, but the net effect on employment is positive.

Second, environment protection has grown rapidly to become a major sales-generating, job-creating industry—\$300 billion/year and 5 million jobs in 2003.

Third, most of the 5 million jobs created are standard jobs for accountants, engineers, computer analysts, clerks, factory workers, etc., and the classic environmental job (environmental engineer, ecologist, etc.) constitutes only a small portion of the jobs created. Most of the persons employed in the jobs created may not even realize that they owe their livelihood to protecting the environment.

Fourth, at the state level, the relationship between environmental policies and economic/job growth is positive, not negative. States can have strong economies and simultaneously protect the environment.

Finally, environmental jobs are concentrated in manufacturing and professional, information, scientific, and technical services, and are thus disproportionately the types of jobs all states seek to attract.

## 1. Introduction: the issue

The relationship between environmental protection (EP), the economy, and jobs has been an issue of harsh contention for decades. Analysts and policymakers of all points of view seem to agree that a strong relationship

exists between EP and jobs; the debate is over the sign of the correlation coefficient. Does EP tend to harm the economy and destroy jobs or to facilitate economic growth and create jobs? If the latter is the case, can the positive affects be quantified and estimated at a meaningful level of detail?

Here, we address this issue by summarizing the initial results of the Jobs and the Environment Initiative, a research effort funded by nonprofit foundations designed to quantify the relationship between EP, the economy, and jobs.<sup>1</sup> We estimate the size of the US environmental

<sup>☆</sup>This paper finds that, contrary to the conventional wisdom, environmental protection has evolved into a major US industry, that most of the 5 million jobs created are for occupations not related to the environment, and that detailed economic and employment impacts can be estimated for individual states.

4 Wisconsin.

## 5 2. Previous studies

6 Numerous studies have been undertaken over the past  
7 two decades to estimate the economic and employment  
8 effects of EP. These can be grouped into three types: (i)  
9 theoretical analyses and cases studies, (ii) econometric  
10 simulations of policy alternatives, and (iii) empirical  
11 estimates derived using historical data. Below we review  
12 some of the major studies in each category.

### 13 2.1. Theoretical analyses and cases studies

14 In 1992, Meyer analyzed the impact of environmental  
15 legislation on differential interstate rates of economic  
16 performance and tested the hypothesis that pursuit of  
17 environmental quality hinders economic growth and job  
18 creation (Meyer, 1992). He ranked the 50 states on the  
19 basis of the stringency of their environmental laws and then  
20 compared the environmental rankings with measures of  
21 economic growth and job creation between 1973 and 1989.  
22 He found no evidence to support a negative relationship  
23 between environmental regulation and economic perfor-  
24 mance, and his results showed the opposite. Meyer found  
25 that the states with the most ambitious environmental  
26 programs had the highest levels of economic growth and  
27 job creation over the period.

28 In 1993 and 1995, Bezdek examined the available  
29 empirical evidence and found that, contrary to conven-  
30 tional wisdom, strict environmental regulations do not  
31 damage US industry, reduce international competitiveness,  
32 or cost thousands of jobs, and he found that strict  
33 environmental standards may even foster economic devel-  
34 opment (Bezdek, 1993). He concluded that recent major  
35 empirical studies reject the hypothesis that there is a  
36 negative relationship between EP and economic and job  
37 growth.

38 During the 1990s, Goodstein conducted several studies  
39 examining the relationship between EP and employment  
40 (Goodstein, 1994). He examined the impact of existing  
41 regulations on overall employment rates, shutdowns and  
42 layoffs, regulation-induced capital flight, estimates of the  
43 costs of environmental regulation, and specific industries  
44 and case studies. He found that little empirical evidence  
45 exists that environmental regulation destroys jobs and that  
46 ex ante estimates of the costs of compliance have been  
47 much higher than actual costs. He also showed the  
48 conditions under which EP might lead to increased  
49 employment.

50 In 1995, Templet hypothesized that the economy is  
51 dependent on the environment to provide resources and  
52 accept wastes, and that a healthy environment should make  
53 for a better economy (Templet, 1995). He cited empirical

evidence from a number of studies substantiating that  
54 finding and showing that states with lower pollution levels  
55 and better environmental policies generally have more jobs,  
56 better socioeconomic conditions, and are more attractive to  
57 new business. He conducted a case study of Louisiana case  
58 that found that jobs increased while pollution declines. He  
59 concluded that there is little evidence that progressive  
60 environmental policies are detrimental to a state's economy  
61 and that there is substantial evidence that the converse is  
62 true.

63 In 1995, Repetto reported that EP requirements have not  
64 contributed to job loss or reduced international competi-  
65 tiveness for US companies. He also found that firms with  
66 superior environmental performance are no less profitable  
67 than others in the same industry (Repetto, 1995). He  
68 concluded that appropriate US environmental policies  
69 could protect the environment with far greater economic  
70 efficiency.

71 In 1997, Berman analyzed the regulation of air pollution  
72 in manufacturing plants in Los Angeles. He examined  
73 employment growth in the Los Angeles region in plants  
74 subject to these regulations, and compared growth at these  
75 plants to employment growth at similar plants in Texas and  
76 Louisiana. He found that, while the Los Angeles regula-  
77 tions imposed costs on regulated plants, they had little  
78 effect on employment and that there were no large job  
79 losses due to these regulations. His major finding was that  
80 the most severe episode of increased air quality regulation  
81 of manufacturing industries did not have a large effect on  
82 manufacturing employment.

83 In 1998, Morgenstern, Pizer, and Shih examined the  
84 possibility that workers could be adversely affected in  
85 heavily regulated industries, which has led to claims of a  
86 "jobs vs. environment" tradeoff (Morgenstern et al., 1998).  
87 They explored how increased environmental stringency can  
88 influence the industry-level demand for labor and devel-  
89 oped estimates for four heavily polluting industries (pulp  
90 and paper, plastics, petroleum refining, and iron and steel).  
91 Their results indicated that increases in environmental  
92 spending do not cause job loss. Their model showed that  
93 the overall demand effect is mitigated by employment  
94 increases associated with new environmental spending.

95 In 1999, Arnold, Forrest, and Dujack examined claims  
96 about the costs of environment regulations by reviewing  
97 the available research (Arnold et al., 1999). They found  
98 that, while the claims about damage to the economy can  
99 mostly be attributed to misinformed advocates or ex-  
100 aggeration, the majority of the fault lies in a lack of  
101 accurate communication of economists' findings about the  
102 effect of environmental regulation to the general public.  
103 Worst-case economic impact scenarios for a regulation—  
104 such as potential increases in unemployment and plant  
105 closures—are reported not as low probabilities, but as  
106 serious threats. They concluded that the view that  
107 environmental regulation seriously harms the US economy  
108 is not supported by the data.

1 In 1999, Bliese reviewed dozens of well-designed studies  
2 that tested the assertion that EP harms the economy  
3 (Bliese, 1999). The results of these studies indicate that EP  
4 normally has no negative impact on the economy overall,  
5 and often has a positive effect. He noted that the studies  
6 only searched for economic impacts of environmental  
7 policies—and found none; they did not estimate environ-  
8 mental or public health benefits. He concluded that the  
9 “environment vs. the economy trade-off” is a myth, even in  
10 narrowly economic terms.

11 In 1999, Yapijakis found that widespread fears of job  
12 losses from EP are unfounded and that, when job creation  
13 aspects of pollution control policies are factored in, EP has  
14 increased net employment in the US (Yapijakis, 1999)  
15 Further, actual layoffs due to regulation have been  
16 extremely small. EP raises employment levels and provides  
17 some recession-proof stimulus to aggregate demand.  
18 Government data reveal that few manufacturing plants  
19 are shut down as a result of environmental or safety  
20 regulations.

21 In 2000, Renner found that creating an environmentally  
22 sustainable economy has already generated an estimated 14  
23 million jobs worldwide (Renner, 2000). He reported that  
24 many new opportunities for job creation are emerging,  
25 ranging from recycling and remanufacturing of goods, to  
26 greater energy and materials efficiency and the develop-  
27 ment of renewable energy. Jobs are more likely to be at risk  
28 where environmental standards are low. He concluded that  
29 investing in the environment, in renewable energy, and  
30 energy efficiency will generate more jobs than investing in  
31 extractive industries and fossil fuels.

## 33 2.2. Econometric simulations of policy alternatives

35 In 1989, Arvind Teotia and his associates estimated the  
36 macroeconomic impacts of the use of clean diesel engine  
37 technology in light trucks to comply with corporate  
38 average fuel economy (CAFÉ) standards. They assumed  
39 that the new engines would capture 15 percent of the light  
40 truck market and estimated that by 2022, between 70,000  
41 and 110,000 jobs would be created (Teotia et al., 1999).

43 In 1989, Bezdek and Wendling simulated the impact of  
44 the two major acid rain control bills that were then being  
45 considered in the US Congress (Bezdek and Wendling,  
46 1989). They found that between 100,000 and 195,000 net  
47 jobs would be created, depending on which bill was  
48 enacted. Economic and job impacts were estimated for  
49 each state and employment requirements by occupation at  
50 the national level were also estimated.

51 In 1990, Jorgensen and Wilcoxon estimated the impact of  
52 environmental regulations on the US economy by simulat-  
53 ing the growth of the economy between 1974 and 1985 with  
54 and without these regulations (Jorgenson and Wilcoxon,  
55 1990). They concluded that the effect of these regulations  
56 was that the economy grew 0.2%/year more slowly than it  
57 would have otherwise, and that by the early 1990s GNP  
58 was about 2.5% less. In 1993, they extended the analysis to

59 assess the impacts of the Clean Air Act Amendments of  
60 1990 and concluded that the net impact of the Amend-  
61 ments would further reduce the rate of growth of GNP  
62 (Jorgenson et al., 1993). They did assess the benefits of EP  
63 or estimate employment impacts.

64 In 1990, a Motor Vehicles Manufacturers Association  
65 study of the potential impact of increased CAFE standards  
66 predicted that tighter CAFE standards would result in the  
67 loss of between 159,000 and 315,000 jobs in the motor  
68 vehicle industry (Motor Vehicle Manufactures Association,  
69 1990). Secondary effects from consumer fuel savings were  
70 not estimated and the report did not consider that fuel  
71 savings by consumers would result in additional spending  
72 on other products and higher employment in the affected  
73 industries.

74 In 1992, Geller, DeCicco, and Laitner estimated the  
75 impact of a “high efficiency” scenario for the energy-using  
76 sectors of the economy and found that a national strategy  
77 of investment in environmentally benign energy sources  
78 and energy efficiency would create one million net new jobs  
79 in the United States within 10 years (Geller et al., 1992).  
80 They also found that by increasing the fuel efficiency of  
81 passenger cars from 28 mpg in 1990 to 40 mpg in 2000 and  
82 50 mpg in 2010, 244,000 additional jobs would be created  
83 by 2010.

84 In 1993, MISI simulated the impact that the environmental  
85 provisions of the North American Free Trade Agreement  
86 would have on US exports and jobs (Management  
87 Information Services, Inc., 1993). The study estimated that  
88 by 2000, NAFTA would generate \$3.8 billion in US  
89 environmental export sales to Mexico and create nearly  
90 70,000 jobs in the US Jobs estimates were disaggregated by  
91 state.

92 During the 1990s, Laitner, DeCicco, Elliott, Geller,  
93 Goldberg, Morris, and Nadel examined energy consump-  
94 tion patterns in the four-state Midwest region of Illinois,  
95 Indiana, Michigan, and Ohio and the states of New York,  
96 New Jersey, and Pennsylvania, and projected energy  
97 consumption through 2010 assuming business-as-usual  
98 policies and trends (Laitner et al., 1994). They then  
99 developed an energy efficiency scenario assuming more  
100 aggressive implementation of energy efficiency measures  
101 and analyzed the potential economic benefits of the  
102 scenario. They found that by 2010, the energy efficiency  
103 scenario would create 132,000 net new jobs in Midwest  
104 region and 164,000 net new jobs in New York, New Jersey,  
105 and Pennsylvania.

106 In 1999, Bernow, Cory, Dougherty, Duckworth, Kartha,  
107 and Ruth examined the impact of implementing a set of  
108 integrated policies designed to bring the US in compliance  
109 with the Kyoto Protocol (Bernow et al., 1999). They found  
110 that the US could reduce its carbon emissions to its Kyoto  
111 target and that the prescribed policies would produce net  
112 economic savings. Specifically, they estimated that by 2010  
113 almost 900,000 net new jobs would be created, relative to  
114 the baseline.

1 A 2001, a Friedman study for the Union of Concerned  
 2 Scientists analyzed the effects of increasing CAFE stan-  
 3 dards to 40 mpg by 2012 and to 55 mpg by 2020 (Friedman  
 4 et al., 2001). UCS estimated that employment, wages, and  
 5 income would increase over the 10–20-year horizon of the  
 6 study. By 2010, the analysis projected a net increase of over  
 7 40,000 jobs; by 2020, the study projected an increase of  
 8 104,000 jobs. In a 2002 update of this study, UCS  
 9 highlighted the potential job gains by industry and state  
 10 resulting from increased CAFE standards, and estimated  
 11 that 183,000 new jobs would be generated (Union of  
 12 Concerned Scientists, 2002).

13 In 2002, research staff at the University of Illinois  
 14 analyzed the Midwest's Clean Energy Development Plan,  
 15 which advocated energy efficient technologies and devel-  
 16 opment of renewable energy resources, especially wind  
 17 power and biomass energy (Regional Economics Applica-  
 18 tions Laboratory, 2002). They estimated that implementing  
 19 the plan would create more than 200,000 new jobs across  
 20 the 10-state Midwest region by 2020.

21 In 2002 and 2004, Barret and Hoerner assessed the  
 22 impact of a set of policies designed to provide steady  
 23 increases in energy efficiency and reductions in carbon  
 24 emissions, while improving overall economic efficiency  
 25 (Barrett and Hoerner, 2002). They analyzed the macro-  
 26 economic impact of these policies and estimated that an  
 27 additional 660,000 net jobs would be created in 2010 and  
 28 1.4 million in 2020. This would increase employment in the  
 29 service sector and reduce the rate of decline in employment  
 30 in manufacturing.

31 In 2004, the New Apollo Initiative proposed an  
 32 economic development plan for the US based on diversify-  
 33 ing energy sources, making the US less dependent on  
 34 foreign oil, investing in industries of the future, promoting  
 35 construction of energy efficient buildings, and investing in  
 36 cities and communities (New Energy for America, 2004). It  
 37 estimated that a \$30 billion investment per year for 10  
 38 years would add more than 3.3 million jobs to the economy  
 39 and stimulate \$1.4 trillion in new GDP.

40 In 2004, UCS analyzed the effects of implementing a  
 41 national renewable electricity standard (RES) that would  
 42 require electric utilities to supply a set percentage of their  
 43 electricity from renewable sources (Union of Concerned  
 44 Scientists, 2004). It found that a under a national RES of  
 45 20% by 2020, the US would increase its total renewable  
 46 power capacity by nearly 11 times over present levels and  
 47 would create more than 355,000 new jobs.

48 In 2004, Levinson and Taylor examined the effect of  
 49 environmental regulations on trade flows by developing an  
 50 economic model to demonstrate how unobserved hetero-  
 51 geneity, endogeneity, and aggregation issues bias measure-  
 52 ments of the relationship between regulatory costs and  
 53 trade (Leninson and Taylor, 2004). They applied an  
 54 estimating equation derived from the model to data on  
 55 US regulations and net trade flows among the US, Canada,  
 56 and Mexico for 130 manufacturing industries from 1977 to  
 57 1986. Their results indicated that industries whose abate-

ment costs increased most experienced the largest increases  
 in net imports. For the 20 industries hardest hit by  
 regulation, the change in net imports they ascribed to the  
 increase in regulatory costs amounted to more than half of  
 the total increase in trade volume over the period.

In 2005, Bezdek and Wendling estimated the economic  
 impacts on the US of enhanced CAFE standards and  
 found that such changes would have positive economic  
 effects and create 300,000 jobs, although the costs in terms  
 of vehicle characteristics and prices and limited consumer  
 choice could be significant (Bezdek and Wendling, 2005).  
 There would be widespread job displacement and job  
 impacts were disaggregated by industry, state, and  
 occupation.

### 2.3. Empirical estimates of actual environmental employment

For two decades, Environmental Business International  
 has been publishing estimates of the size of the US  
 environmental industry with times series data beginning  
 in 1970. The data are disaggregated by Services (analytical  
 services, wastewater treatment, solid waste, hazardous  
 waste, remediation, and consulting and engineering),  
 Equipment (water and chemicals, instruments and infor-  
 mation, air pollution control, waste management, and  
 process and prevention), and resources (water utilities,  
 resource recovery, and clean energy systems and power).  
 EBI estimates that the size of the US environmental  
 industry has increased from \$18 billion in 1970 to \$227  
 billion in 2003. Corresponding employment or jobs  
 numbers are not published.<sup>2</sup>

MISI has been estimating the economic and jobs impact  
 of the environmental industry for two decades.<sup>3</sup> Using an  
 econometric input–output (I–O) model to estimate the  
 direct and indirect impact of the industry, MISI estimates  
 that EP has increased from \$39 billion in sales (2003  
 dollars) and 700,000 jobs in 1970 to \$300 billion (2003

 Services, Inc., *Jobs and Economic Opportunities in the U.S. Created by  
 Environmental Protection*. Periodic reports, 1986–2004.

dollars) and 5 million jobs in 2003—see the discussion in Section 5.

In 2001, MISI analyzed the environmental industry and jobs in six Midwestern states: Illinois, Iowa, Michigan, Minnesota, Ohio, and Wisconsin.<sup>4</sup> It found that in 1998, environment-related employment in these states totaled 893,000 widely distributed among sectors, industries, jobs, and skills. Jobs estimates were disaggregated among each of the six states.

In 1999, the US International Trade Administration (ITA) estimated the world market for environmental products and services and the size of the US market, including estimates at the state and metropolitan statistical area (MSA) levels.<sup>5</sup> ITA estimated that the 1999 US environmental market totaled \$189 billion, almost 38% of the global \$499 billion market. In meeting the demands of those markets, the US environmental industry was estimated to have generated \$196 billion of revenues and over 1.4 million jobs. The ITA US employment estimates were disaggregated by state and by selected MSAs.

The Census MA200 survey has been one of the more respected sources for information on the US environmental industry.<sup>6</sup> This report was not available for a number of years after 1994, but was revived for 1999. The MA200 results are not consistent with previous reports, but they presented a snapshot of major portions of the environmental industry by detailed North American Industry Classification System (NAICS) industry and by state. However, the survey's biggest weakness is that it only covers the mining (NAICS 21), manufacturing (NAICS 31-33), and electric power generation industries (NAICS 22111). Thus, while the survey estimates are of sufficient quality, they lack comprehensiveness and describe only a fraction of the environment-related business activities in the US. Pollution abatement costs were disaggregated by capital expenditures and operating costs, but employment estimates were not included.

### 3. Methodology

The economic and employment effects of EP expenditures were estimated using the Management Information Services, Inc. model, database, and information system. A simplified version of the MISI model as applied in this study is shown in Fig. 1.

The first step involves translation of environmental expenditures into per unit output requirements from every

industry in the economy. Second, the direct output requirements of every industry affected by the expenditures are estimated, and they reflect the production and technology requirements implied by the environmental spending. These direct requirements show, proportionately, how much an industry must purchase from every other industry to produce one unit of output. Direct requirements, however, give rise to subsequent rounds of indirect requirements. The sum of the direct plus the indirect requirements represents the total output requirements from an industry necessary to produce one unit of output.

Economic I-O techniques allow the computation of the direct and the indirect production requirements. Direct industry output requirements are converted into total output requirements from every industry by means of the I-O inverse equations. These equations show not only the direct requirements, but also the second, third, fourth,  $n$ th round indirect industry and service sector requirements resulting from environmental expenditures. Next, the total output requirements from each industry are used to compute sales volumes, profits, and value added for each industry. Then, using data on manhours, labor requirements, and productivity, and employment requirements, the number of jobs created within each industry are estimated.

The next step requires the conversion of total employment requirements by industry into job requirements for specific occupations and skills. To accomplish this, MISI utilizes data on the occupational composition of the labor force within each industry and estimates job requirements for 700 occupations encompassing the entire US labor force. This permits estimation of the impact of environmental expenditures on jobs for specific occupations.

Utilizing the modeling approach outlined above, the MISI model allows estimation of the effects on employment, personal income, corporate sales and profits, and government tax revenues in the US. Estimates can then be developed for detailed industries and occupations.

The final step in the analysis required assessing the economic impacts on individual states, which were estimated using the MISI regional model, which allows the flexibility of specifying multi-state, state, or county levels of detail. Because of the comprehensive nature of the modeling system, these regional impacts are consistent with impacts at the national level.

### 4. What constitutes an environmental job?

#### 4.1. Ambiguities and questions

As discussed below, we estimate that EP created nearly 5 million jobs in the US in 2003, and these were distributed widely throughout all states and regions within the US. But how many of these are “environmental jobs” or “green jobs?” More specifically, what constitutes an “environmental job?” While a definitive analysis of this important

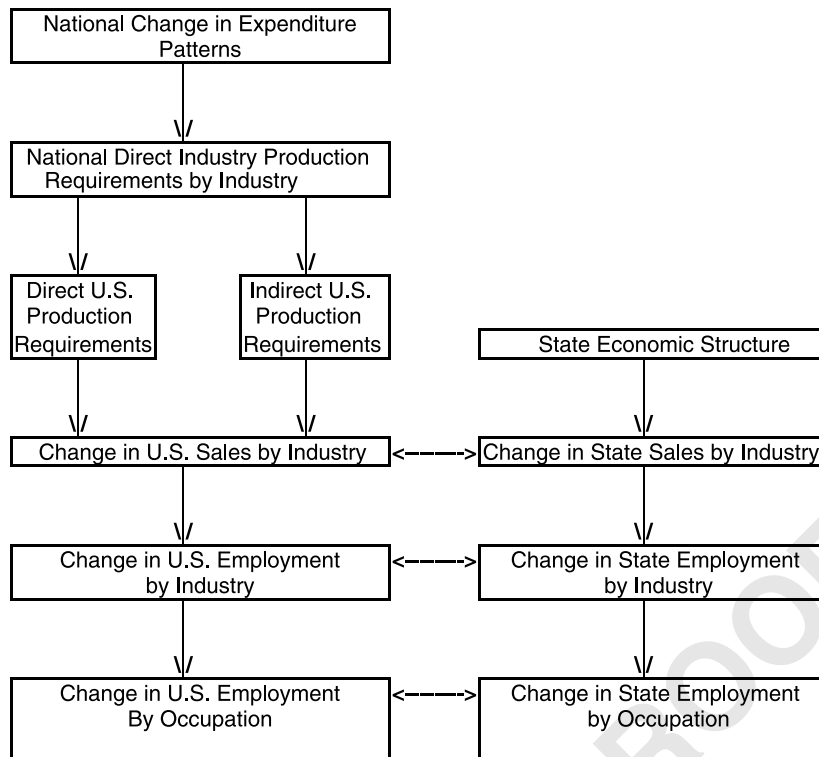

Fig. 1. Use of the MISI model to estimate the economic, employment, and occupational impacts of environmental protection. *Source:* Management Information Services, Inc., 2006.

topic is outside the scope of this report, our review of the literature indicates that there is no rigorous, well-accepted definition of an environmental job. Rather, the definitions used are often loose and contradictory.

Clearly, an ecologist or an environmental engineer would constitute an environmental job, as would an employee of the federal or a state EP agency. However, there are ambiguities. For example, most people would agree that the positions in a firm that assembles and installs solar thermal collectors would be considered environmental jobs. But what about the jobs involved in producing those solar panels, especially if the factory involved used coal-based energy, one of the most controversial fossil fuels in terms of emissions? Here, these manufacturing jobs are included as jobs created indirectly by environmental expenditures.

Most analysts would consider jobs in a recycling plant to be environmental jobs. But what if the recycling plant itself produces air pollution? What about a firm in North Carolina that produces emissions control equipment for power plants in Alabama? It seems clear that the jobs in the North Carolina company should be considered green or environmental jobs, even though the user of the equipment in Alabama may cause pollution in North Carolina. What about environmental engineers and environmental controls specialists working in a coal-fired power plant? What about the workers who produce environmental control equipment for the plant?

There are many firms in the US that produce products for the automotive industry. Should those that produce components for fuel-efficient vehicles be considered part of the environmental industry, but not those that produce components for gas guzzlers? If so, is there any way to accurately distinguish between these? Should all factories producing catalytic converters be considered environmental jobs, even when some of these converters are used on low miles-per-gallon vehicles?

These relevant questions have, in fact, been generated by shifts in environmental policy itself. The early stages of the environmental movement in the 1970s and 1980s focused primarily on “end-of-the pipe” solutions: The remedies focused on cleaning or minimizing air, water, or solid waste pollutants after they had been produced. However, EP has evolved to include entire processes, so, rather than cleaning up at the end of the pipe, the entire manufacturing and servicing processes are being designed to minimize the production of pollutants. Therefore, it is possible that efficient processes designed to produce relatively little waste output could actually result in a decrease in the number of “environmental” jobs if these are defined strictly as “end of the pipe” jobs. Energy efficiency could ultimately result in less need for electric power and could result in the shutting down of a coal-fired electric power plant. While some may view such a shutdown as an environmental plus, many environmental jobs in that power plant involving pollution abatement would be in this case lost.

1 While solid waste abatement is a major area of  
 2 environmental concern, does this imply that all persons  
 3 engaged in trash collection are performing environmental  
 4 jobs? What part of the tourism industry constitutes  
 5 “ecotourism,” and are all jobs associated with ecotourism  
 6 green jobs? Are forms of alternative energy green  
 7 industries, with all jobs counting as environmental jobs?

8 There is also the issue of how to account for indirect job  
 9 creation and how broadly or narrowly to define an indirect  
 10 environmental job. For example, what of ancillary jobs  
 11 created across the street from a factory producing solar  
 12 collectors, such as those in a fast food restaurant, dry  
 13 cleaner, etc. whose customers are primarily the workers at  
 14 the renewable energy factory. Are these latter jobs also  
 15 considered to be “indirect” green jobs or environmental  
 16 jobs? We include such indirect jobs here.

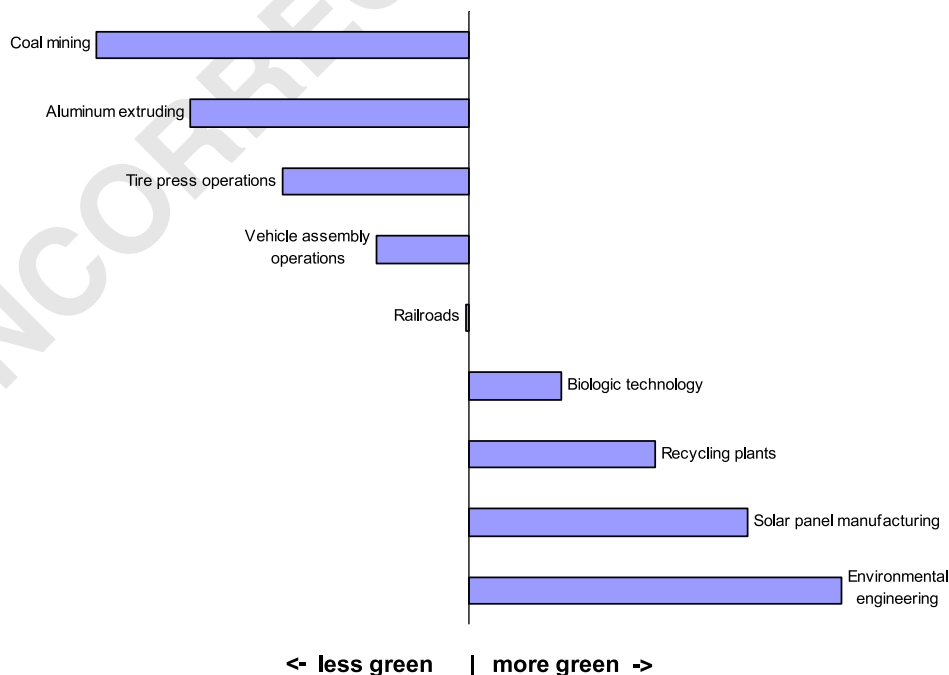

#### 17 4.2. Definitions and concepts used here

18 Here, we consider that jobs can be considered to be  
 19 “green” relative to the way the job was performed  
 20 previously, i.e., in a production process, a change in  
 21 technology that reduces waste emissions or energy con-  
 22 sumption makes the jobs in that process “greener” than  
 23 before. Based on extensive research and literature review,  
 24 we determine that environmental jobs are best understood  
 25 when viewed in a continuum, with jobs that generate  
 26 environmental degradation or extraction at one end; a  
 27 range of greener jobs involving clean production measures  
 28 and technologies to reduce environmental impacts in the  
 29 center, and the other end of the spectrum where jobs have a  
 30 positive environmental impact (see Fig. 1). Using this  
 31 concept, we define environmental industries and green jobs

32 as those which, as a result of environmental pressures and  
 33 concerns, have produced the development of products,  
 34 processes, and services, which specifically target the  
 35 reduction of environmental impact. Environment-related  
 36 jobs include those created both directly and indirectly by  
 37 EP expenditures (Fig. 2).

38 There exists relatively little rigorous research addressing  
 39 the practical relationship between EP and job creation.  
 40 Even some research in this area sponsored by environ-  
 41 mental organizations is off the mark, in that it has tended  
 42 to emphasize jobs creation in classically green activities,  
 43 such as environmental lawyers or workers in recycling  
 44 plants. However, while these jobs count as jobs related to  
 45 the environment, we found that classic environmental jobs  
 46 constitute only a small portion of the jobs created by EP.  
 47 The vast majority of the jobs created by EP are standard  
 48 jobs for accountants, engineers, computer analysts, clerks,  
 49 factory workers, truck drivers, mechanics, etc. In fact, most  
 50 of the persons employed in these jobs may not even realize  
 51 that they owe their livelihood to protecting the environ-  
 52 ment. For example, as illustrated in Fig. 3, in the US in  
 53 2003, we estimate that EP created: More jobs for  
 54 secretaries (97,900) than for environmental scientists  
 55 (50,700); more jobs for management analysts (82,600) than  
 56 for environmental engineers (45,200); more jobs for book-  
 57 keepers (71,600) than for hazardous materials workers  
 58 (33,300); more jobs for janitors (56,400) than for environ-  
 59 mental science technicians (25,000); more jobs for compu-  
 60 ter systems analysts (30,000) than for chemical engineers  
 61 (8,200); and more jobs for truck drivers (25,200) than for  
 62 biological technicians (12,100).

63 More generally, arguments stressing the economic  
 64 benefits and job creation resulting from EP and clean

65 Fig. 2. The environmental job spectrum. Source: Management Information Services, Inc., 2006.

Fig. 3. Selected US jobs created in 2003 by environmental expenditures. *Source:* Management Information Services, Inc., 2006.

energy initiatives are not currently being made in a rigorous manner, which disaggregates these benefits to a level of detail that is meaningful to policymakers. The level of detail required is at the sector, industry, state, city, and county level, and the jobs created have to be identified by industry, category, skill, and specific occupation at the state and local level. The findings summarized here provide data at such levels of detail.

#### 4.3. Jobs distribution in typical environmental companies

There are thousands of environmental companies located throughout the US and they generate jobs for nearly 5 million workers in virtually every community. These firms range from the very small one or two person “mom and pop” shops to very large firms employment thousands of workers; they employ workers at all levels of skills, from the most basic and rudimentary to the very high skilled technical and professional; include environmental service firms and manufacturing firms; include those whose market is local, those whose market is state and regional, those who market is national, and those whose market is international, and they face the same problems, challenges, and opportunities as other companies

Given the wide diversity in the size, function, and technologies of environmental companies, it is impossible to estimate the job profile of the “average” environmental firm. However, it is possible to identify the jobs and earnings profiles of typical types of firms involved in environment-related areas of work. Table 1 shows the 2003 occupational job distribution and employee earnings of a typical environmental remediation services company; Table 2 shows the same data for a typical wind turbine

manufacturing company. These tables illustrate the points made above.

First, firms working in the environmental and related areas employ a wide range of workers at all educational and skills levels and at widely differing earnings levels.

Second, even in environmental companies, most of the employees are not classified as “environmental specialists.” For example, in the environmental remediation services firm profiled in Table 1, most of the workers are in occupations such as laborers, clerks, bookkeepers, accountants, maintenance workers, cost estimators, etc. All of these employees owe their jobs and livelihoods to EP, but, in general, they perform the same types of activities at work as employees in firms that have little or nothing to do with the environment.

This is illustrated even more forcefully in Table 2. The occupational job distribution of a typical wind turbine manufacturing company differs relatively little from that of a company that manufactures other products. Thus, the production of wind turbines and components requires engine assemblers, machinists, machine tool operators, mechanical and industrial engineers, welders, tool and die makers, mechanics, managers, purchasing agents, etc. These are “environmental” workers only because the company they work for is manufacturing a renewable energy product. Importantly, with the current national angst concerning the erosion of the US manufacturing sector and the loss of US manufacturing jobs, it is relevant to note that many environmental and renewable energy technologies are growing rapidly.<sup>7</sup>

<sup>7</sup>For example, windpower is the most rapidly growing source of electrical power in the world.

## 5. Findings at the national level

We found that, contrary to general public perception and public policy understanding, since the late 1960s,

protection of the environment has grown rapidly to become a major sales-generating, profit-making, job-creating industry. Expenditures in the US for EP have grown (in constant 2003 dollars) from \$39 billion per year

1 Table 3  
 2 Environmental protection expenditures and jobs in the us economy,  
 3 1970–2003

	Expenditures (billions of 2003 dollars)	Jobs (thousands)
7 1970	\$39	704
7 1975	77	1352
9 1980	121	2117
9 1985	158	2838
11 1990	204	3517
11 1995	235	4255
13 2003	\$301	4974

13 Source: Management Information Services, Inc., 2006.

15  
 17 in 1970 to \$301 billion per year by 2003—increasing more  
 18 rapidly than GDP over the same period—see Table 3. If  
 19 “EP” were a corporation, it would rank higher than the top  
 20 of the Fortune 500, for our estimate of 2003 EP  
 21 expenditures (\$301 billion) ranks it higher than the sales  
 22 of \$259 billion for Wal-Mart, the largest corporation in the  
 23 US In 2003, EP generated five million jobs distributed  
 24 widely throughout the nation.

25 Many companies, whether they realize it or not, owe  
 26 their profits—and in some cases their existence—to EP  
 27 expenditures.<sup>8</sup> Many workers, whether they realize it or  
 28 not, would be unemployed were it not for these expendi-  
 29 tures: In 2003, EP created nearly five million jobs  
 30 distributed widely throughout the nation. To put this into  
 31 perspective, the size of environment-related employment is  
 32 over ten times larger than employment in the US  
 33 pharmaceuticals industry, nearly six times larger than the  
 34 apparel industry, almost three times larger than the  
 35 chemical industry, nearly half the employment in hospitals,  
 36 and almost one-third the size of the entire construction  
 37 industry.

38 We estimate that in 2003 protecting the environment  
 39 generated \$301 billion in total industry sales, \$20 billion in  
 40 corporate profits, 4.97 million jobs, and \$45 billion in  
 41 Federal, state, and local government tax revenues.<sup>9</sup> Clearly,  
 42 providing the goods and services required for EP has  
 43 become a major US industry with significant effects on the

44 <sup>8</sup>In this paper, “expenditures” refers to all public and private spending in  
 45 the environmental sector (EP spending) and is used interchangeably with  
 46 “sales.”

47 <sup>9</sup>The national estimates have been developed by MISI beginning in 1986  
 48 using the model and database summarized in Section 2, and have been  
 49 updated periodically over the past two decades. The six states discussed  
 50 here were selected for detailed analysis at the request of the funders of the  
 51 work. The overall project goal is to eventually conduct similar analyses for  
 52 as many states as possible and, at present, estimates are being developed  
 53 for three more states—Arizona, California, and Connecticut—to provide  
 54 better geographic coverage. In addition, analyses for states such as New  
 55 York, Oregon, and Washington that have traditionally been viewed as  
 56 environmentally aggressive can help determine if environmental job  
 57 growth has been more rapid in these states. Findings will be posted on the  
 MISI web site when available: [www.misi-net.com](http://www.misi-net.com)

national economy and labor market and on those of  
 individual states.<sup>10</sup>

## 6. Findings at the state level

As part of the research initiative we have thus far  
 estimated and assessed the environmental industry and  
 jobs in six states: Florida, Michigan, Minnesota, North  
 Carolina, Ohio, and Wisconsin.<sup>11</sup> Our findings are  
 summarized in Tables 4 and 5.

### 6.1. Aggregate and sectoral findings

Table 4 summarizes the parameters of the environmental  
 industries in each state. The size of the industry in each  
 state differs considerably, from \$5.4 billion in Wisconsin to  
 \$15.4 billion in Florida, generally corresponding to the  
 differences in state GDP. However, the industry share of  
 state GDP differs from a high of 3.9% in Michigan to a  
 low of 2.6% in Minnesota. Similarly, environment-related  
 employment ranges from 220,000 in Florida to 92,000 in  
 Minnesota—again reflecting mainly the differences in the  
 sizes of the state labor forces. Environmental employment  
 ranges from a high of 4.9% of total employment in Ohio to  
 2.9% in North Carolina.

The shares of each state of the total US environmental  
 industry and environment-related jobs also differ substan-  
 tially, depending largely on the size of state GDP and labor  
 force. Nevertheless, there are some important differences  
 among the states. For example, while the number of  
 environment-related jobs is about the same in both  
 Michigan and Florida and each state has about 4.4% of  
 the national total, the population of Florida is nearly twice  
 that of Michigan—Florida represents about six percent of  
 the US population while Michigan comprises 3.4%. That  
 is, per capita, the size of the environmental industry in  
 Michigan is nearly twice that of the industry in Florida.

Table 5 shows the industry sector distribution of total  
 employment and of environmental employment in each of  
 the six states. It and Table 4 illustrate that environment-  
 related jobs are distributed among all sectors, but are  
 heavily concentrated in several. Significant portions of the  
 environmental jobs in each state are in the public  
 administration sector which, given the public nature of  
 EP, is to be expected. However, most of the environmental  
 jobs in the states are in the private sector, and focusing on  
 these reveals that they are heavily concentrated in several  
 sectors.

<sup>10</sup>As discussed, all estimates of the size of the environmental industry  
 rely critically on the exact definition of the industry. Since there is no  
 official definition, estimates of the size of the environmental industry differ  
 according to the source. In MISI’s case, the definition of the industry  
 includes human and environmental sustainability principles, and MISI’s  
 estimates thus include a broader range of environmental activities in the  
 economy than some other definitions that have been developed.

<sup>11</sup>The detailed findings for each state are available on the MISI web site:  
[www.misi-net.com](http://www.misi-net.com)

Table 4  
Summary of the environmental industries in six states in 2003

	Environmental industry (billions) (\$)	Environmental jobs	Environmental industry as a percent of		State environmental industry as a percent of		Private sector environmental jobs	
			State GDP (%)	State jobs (%)	Total US environmental industry (%)	Total US environmental jobs (%)	Manufacturing (%)	Professional, scientific, technical (%)
Florida	15.4	220,000	3.1	3.0	5.0	4.4	7	22
Michigan	12.9	217,000	3.9	4.9	4.3	4.4	29	29
Minnesota	5.1	92,000	2.6	3.5	1.7	1.8	21	23
North Carolina	9.1	112,000	3.1	2.9	3.0	2.9	24	20
Ohio	12.2	176,000	3.2	3.3	4.1	3.5	29	25
Wisconsin	5.4	97,000	2.9	3.5	1.8	2.0	31	16

Source: Management Information Services, Inc., 2006.

Of particular note is that the private sector environmental industry is more manufacturing intensive than other average private sector activity in the states. As shown in Fig. 4, in Florida, 7.4% of private sector jobs in the environmental industry is in manufacturing, compared to 6.2% in manufacturing among all private sector jobs in the state; in Michigan, 29% of private sector jobs in the environmental industry is in manufacturing, compared to 17% in manufacturing among all private sector jobs; in Minnesota, the comparable shares are 21% and 15%; in North Carolina, the comparable shares are 24% and 19%; in Ohio, the comparable shares are 29% and 18%; in Wisconsin, the comparable shares are 31% and 21%.

The jobs concentration is even more pronounced with respect to employment in the professional, scientific, and technical services sector. As shown in Fig. 5, in Florida, 22% of private sector environmental jobs is in professional, scientific, and technical services, compared to 6% of all private sector jobs in the state; in Michigan, 29% of private sector environmental jobs is in professional, scientific, and technical services, compared to 8% of all private sector jobs in the state; in Minnesota, the comparable shares are 23% and 5%; in North Carolina, the comparable shares are 20% and 5%; in Ohio, the comparable shares are 25% and 7%; in Wisconsin, the comparable shares are 16% and 4%.

Conversely, there are relatively few private sector environmental jobs in other parts of the states' economies, including retail trade, finance and insurance, health care and social services, and transportation and warehousing.

The concentration of environmental jobs within certain industrial sectors is instructive and interesting. While accounting for only about 3–5% of total employment in each state, the industry sector composition of environmental employment is highly skewed in favor of certain sectors—including manufacturing. This indicates that investments in the environment will provide a greater than proportionate assist to the states' manufacturing sectors. All of these states are seeking to modernize and expand their high-tech industrial and manufacturing bases. Table 5

and Fig. 4 indicate that the environmental industry can aid in this objective.

Similarly, environmental investments generate, proportionately, 3–4 times as many jobs in professional, scientific, and technical services as the state averages. Jobs in this sector include the high-skilled, high-wage, technical, and professional jobs that all states seek to attract and retain. Table 5 and Fig. 5 indicate that investments in EP can be of considerable assistance here.

## 6.2. Environmental jobs by occupation

We disaggregated environmental employment in each state by specific occupations and skills. The results for Florida and Michigan are representative of those for the six states, and this information for selected occupations is given in Tables 6 and 7. These tables illustrate that environmental jobs are widely distributed among all occupations and skill levels and, while the number of jobs created in different occupations differs substantially, employment in virtually all occupations is generated by environmental spending.

As noted in Section 4, the vast majority of the jobs created by EP are standard jobs for accountants, engineers, computer analysts, clerks, factory workers, truck drivers, mechanics, etc., and most of the persons employed in these jobs may not even realize that they owe their livelihood to protecting the environment. This is further illustrated in Tables 6 and 7, which list the jobs created by EP in Florida and Michigan in 2003 within selected occupations. For example, Table 6 shows that EP generated in Florida: More jobs for sheet metal workers (821) than for geoscientists (241); more jobs for office clerks (4968) than for environmental engineers (2545); more jobs for executive secretaries (2432) than for landscape architects (313); more jobs for janitors (1827) than for natural science managers (207); more jobs for electricians (708) than for chemists (242); more jobs for truck drivers (2870) than for septic tank servicers (2181); more jobs for financial managers (684) than for conservation scientists (371); more jobs for

management analysts (2049) than for environmental engineering technicians (1289); and more jobs for computer software engineers (1839) than for hazardous material removal workers (1267).

Table 7 shows similar findings for Michigan. Thus, many workers in Florida and Michigan are dependent on EP for their employment, although they often would have no way of recognizing that connection unless it is brought to their attention.

The importance of environmental spending for jobs in some occupations is much greater than in others. For some occupations, such as environmental scientists and specialists, environmental engineers, hazardous materials work-

ers, water and liquid waste treatment plant operators, environmental science protection technicians, refuse and recyclable material collectors, and environmental engineering technicians, virtually all of the demand in both states is created by EP activities. This is hardly surprising, for most of these jobs are clearly identifiable as “environmental” jobs.

However, in many occupations not traditionally identified as environment-related, a greater than proportionate share of the jobs is also generated by EP. On average, environment-related employment in Florida comprises only 3% of total employment and in Michigan comprises 4.9%, in 2003 EP expenditures generated jobs for a greater

97  
99 drafters, fiberglass laminators and fabricators, forest and  
101 conservation technicians, heating, air conditioning, and  
103 refrigeration mechanics and installers, industrial engineer-  
105 ing technicians, surveying and mapping technicians,  
107 chemical plant and system operators, electrical and  
109 electronics repairers, engine and other machine assemblers,  
111 surveying and mapping technicians, and network systems  
113 and data communications analysts.

107 The above findings are significant for they indicate that  
109 EP creates jobs in greater than proportionate share in two  
111 categories that Florida and Michigan—and other states—  
113 are eager to attract: (i) college-educated professional  
workers, many with advanced degrees, and (ii) highly  
skilled, technical workers, with advanced training and  
technical expertise, many of them in the manufacturing  
sector. EP thus generates jobs that are disproportionately

for highly skilled, well-paid, technical and professional workers, who in turn underpin and provide foundation for entrepreneurship and economic growth.

Our work thus demonstrates that EP can form an important part of a strategy for states based on attracting and retaining professional, scientific, technical, high-skilled, well paying jobs, including manufacturing jobs. While a successful strategy must have other components as well, rarely has any state recognized the economic and jobs benefits that could flow from specifically encouraging the development of environmental and environment-related industries as an economic development initiative. Indeed, usually the opposite is the case: Most states usually tend to view EP as economically negative.<sup>12</sup>

Another important finding derived here is the significance of the environmental industry compared to other sectors of the state economies. For example, the tourism industry generates about 540,000 jobs in the Florida, and this state well recognizes the key role that tourism plays in the state economy. Here, we estimate that environment-related jobs in Florida total 220,000—jobs that tend to be more highly skilled and better paying than those in the tourism sector. This fact is not widely known or appreciated by state policy-makers.

## 7. Comparison to other estimates of environmental spending

Aside from the estimates presented here, the only other comprehensive, consistent time series of estimates of US environmental expenditures over the past four decades are those developed by Environmental Business, International (EBI).<sup>13</sup> The MISI and EBI data series are not strictly comparable. For example, MISI estimates environment-related spending using the expenditure concept and disaggregates spending by media (air, water, land, etc.) and other categories such as R&D, energy-related environmental programs, and so forth. EBI focuses on revenues to business and classifies spending into services (analytical, hazardous waste, consulting & engineering, etc.) equipment (air pollution control, waste management, instruments & information, etc.), and resources (water utilities, resource recovery, and clean energy & power).

<sup>12</sup>These policies differ considerably among the states, and some states have belatedly begun to recognize the economic benefits of environmental protection. For example, Florida has initiated a major Everglades restoration program and has prohibited offshore drilling, Michigan has implemented a hydrogen program, Arizona has aggressively promoted solar and wind, and Washington is initiating an ambitious biomass program.

<sup>13</sup>The EBI data are available for purchase at [www.ebiusa.com](http://www.ebiusa.com). In 1990, EPA published estimates of environmental costs (US Environmental Protection Agency, Office of Policy, Planning, and Evaluation. *Environmental Investments: The Cost of a Clean Environment*. EPA-230-11-90-083, November 1990) and Pace University published estimates of the environmental costs of electricity (Richard Ottinger et al., *Environmental Costs of Electricity*, New York: Oceana publications, 1990). However, no time series data are available for these data and the estimates are not comparable to the MISI estimates.

Table 8

Comparison of estimates of the growth of environmental expenditures in the US (expenditures in billions of 2003 dollars)

	MISI		EBI <sup>a</sup>		
	Expenditures (millions/\$)	Growth (%)	Expenditures (millions)	Growth (%)	
1970	39		73		
1975	77	97	100	37	
1980	121	57	125	25	
1985	158	31	148	18	
1990	204	29	201	36	
1995	235	15	210	5	
2000	273	16	221	5	
2003	301	10	227	3	
2010	357	19	268	18	
2015	398	11	NA <sup>b</sup>		
2020	439	10	NA		

Source: Management Information Services, Inc. and Environmental Business International, Inc., 2006.

<sup>a</sup>EBI expenditures in current dollars were converted by MISI to 2003 dollars.

<sup>b</sup>NA, not available. EBI did not forecast expenditures beyond 2010.

A comparison of the MISI and EBI estimates<sup>14</sup> is given in Table 8, which shows that:

- During the 1970s, the EBI estimates of environmental expenditures were significantly higher than the MISI estimates.
- From 1980 through 1995, the MISI and EBI estimates were roughly comparable
- By 2000, the MISI estimates were larger than the EBI estimates.
- The percentage growth rates in expenditures over the past four decades were roughly comparable, and both data sets show the rate of increase in environmental spending decreasing after 1970.
- The forecast rate of growth of environmental spending through 2010 by both EBI and MISI are nearly identical, although from different bases.
- EBI shows the rate of growth of expenditures to be between three and 5% from 1995 to 2003, whereas MISI shows the rates of growth to be considerably higher, although declining.
- MISI forecasts that from 2010 to 2020, environmental expenditures will increase by 23%, whereas EBI presents no forecasts beyond 2010.

<sup>14</sup>EBI present its estimates in current dollars. For comparison here, MISI converted the EBI current dollar estimates to constant 2003 dollar estimates using the GDP deflator series.

## 1 8. Conclusions and suggestions for further research

### 3 8.1. Findings at the national level

5 Our first major finding is that EP, economic growth, and  
 6 jobs creation can be complementary and compatible:  
 7 Investments in EP can create jobs, not destroy them.<sup>15</sup>  
 8 This finding is important because it differs from what many  
 9 legislators and policy-makers currently believe.

10 Second, contrary to general public perception and public  
 11 policy understanding, since the late 1960s protection of the  
 12 environment has grown rapidly to become a major sales-  
 13 generating, profit-making, job-creating industry—\$300  
 14 billion/year. and 5 million jobs in 2003. The size and the  
 15 job creating potential of the environmental industry is  
 something that few are aware of.

16 Third, the vast majority of the five million jobs created  
 17 by EP are standard jobs for accountants, engineers,  
 18 computer analysts, clerks, factory workers, truck drivers,  
 19 etc., and the classic environmental job (environmental  
 20 engineer, ecologist, conservation technician, etc.) constitu-  
 21 tes only a small portion of the jobs created. In fact, most of  
 22 the persons employed in the jobs created may not even  
 23 realize that they owe their livelihood to protecting the  
 24 environment.

25 This finding is important for, even recognizing that EP is  
 26 good for the economy and is creating 5 million jobs, the  
 27 first impression is likely that these are jobs for environment  
 28 specialists, ecologists, environmental regulators, etc. We  
 29 found that jobs for all occupations and skills are generated,  
 30 and this should be of interest to organized labor, trade and  
 31 professional associations, and policy-makers.

### 32 8.2. Findings at the state level

33 Our first major finding at the state level, derived from  
 34 detailed analyses of the environmental industry and jobs in  
 35 Florida, Michigan, Minnesota, North Carolina, Ohio, and  
 36 Wisconsin, is that the overall relationship between state  
 37 environmental policies and economic/job growth is posi-  
 38 tive, not negative. States can and do have strong economies  
 39 and simultaneously protect the environment, and states  
 40 with the strongest environmental records also have the best

41 <sup>15</sup>While environmental protection both creates and displaces jobs, we  
 42 have found the net jobs effect to be strongly positive, although jobs  
 43 impacts will vary from case to case. Further, even when the net jobs effect  
 44 is strongly positive, it must be recognized that significant job displacement  
 45 may be occurring. For example, in analyzing the likely economic and jobs  
 46 effects of enhanced CAFE standards, we estimated that by 2020 347,000  
 47 net jobs would be created. However, this estimate was the combination of  
 48 total gross job creation of 433,000 jobs and the displacement of 86,000  
 49 jobs. That is, while nearly 350,000 *net* jobs would be created, nearly 90,000  
 50 jobs would still be lost. This has obvious policy implications. See Roger H.  
 51 Bezdek and Robert M. Wendling, "Fuel Efficiency and the Economy,"  
 52 *American Scientist*, op. cit., and Roger H. Bezdek and Robert M.  
 53 Wendling, "Potential Long-term Impacts of Changes in US Vehicle Fuel  
 54 Efficiency Standards," *Energy Policy*, op. cit.

job opportunities and climate for long-term economic  
 development.

This is a key finding. In our analysis of the six states we  
 found that all of them assume that there is a negative  
 relationship between protecting the environment and  
 economic and job growth. Thus, the states' policies relating  
 to EP and economic/job development focus on "reform-  
 ing," "streamlining," and "rationalizing" environmental  
 rules and regulations (a euphemism for weakening them),  
 "simplifying" and "accelerating" environmental permit-  
 ting, and otherwise sacrificing the environment to econom-  
 ic growth and job creation. Hopefully, the research  
 reported here will begin to change these state attitudes  
 and policies.

Second, environmental jobs in each of the states are  
 concentrated within a number of sectors, including  
 manufacturing and professional, information, and scienti-  
 fic, and technical services, and this is significant because  
 the states are seeking to modernize and expand their high-  
 tech industrial and manufacturing bases. Thus, not only is  
 the relationship between EP and jobs positive, but the types  
 of jobs created are disproportionately scientific, profes-  
 sional, technical, high-skilled, manufacturing, and high-  
 wage jobs—the very types of jobs that all states are  
 attempting to retrain and attract. These types of jobs are a  
 prerequisite for a prosperous, middle class society able to  
 support state and local governments with tax revenues—  
 which states already recognize. Of particular note, in the  
 six states studied thus far data show that investments in the  
 environment will provide a greater than proportionate  
 assist to the manufacturing sector.

Finally, EP can form an important part of states'  
 economic development strategies, and there is no inherent  
 institutional impediment in any state to using existing  
 economic assistance policies and incentives to facilitate  
 development of environmental industries and jobs. This is  
 a key policy finding because, at present, none of the states  
 we examined appreciates this potential: (i) no state has  
 integrated environmental industry and job development  
 into its general strategic or economic development plan; (ii)  
 state environmental departments and agencies have little or  
 no focus on environmental employment or job develop-  
 ment; (iii) state labor and workforce departments and  
 agencies have little or no focus on environmental industries  
 or jobs.

Each state is home to diverse environmental companies,  
 many global leaders in their field,<sup>16</sup> but their strong role in  
 employment generation is largely overlooked in economic  
 development initiatives and policy. Altering states' percep-  
 tions and policies here is essential.

<sup>16</sup>As part of this research project, we identified and assessed a  
 representative sample of environmental firms in each state selected for  
 heterogeneity with respect to size, geographic location, and services and  
 products provided. These findings are available on the MISI web site:  
[www.misi-net.com](http://www.misi-net.com)

### 8.3. Suggestions for further research

Our work has identified several areas requiring further research. First, a more rigorous and generally accepted definition of what constitutes an “environment-related job” is required. Environmental advocates have tended to identify the more glamorous types of jobs, such as ecologist, wildlife biologist, conservation specialist, solar energy researcher, etc., but we found that the overwhelming majority of environment-related jobs are for the standard occupations, skills, and professions. Nevertheless, the numbers and types of jobs—both in general and in specific industries and firms—are in need of much additional research.

Second, the empirical work reported here needs to be expanded. While we have analyzed the environmental industries in six states, it remains to be determined how representative our findings are for the rest of the US. At least as important, our analyses of each state were not comprehensive, and much more detailed assessment of several individual states is required. Such an assessment would look in detail below the state level to specific geographic regions and industries and conduct in-depth analyses of specific environmental firms.

Finally, it would be useful to have international perspective. We found that in the US environment-related activities account for 3–5% of national and state GDP and jobs. Using generally consistent concepts and definitions, it would be interesting to determine how these estimates compare to estimates of environmental industries and jobs in other developed nations. International comparative analyses of detailed results at the sector, industrial, and occupational level would be especially useful.
